Red Slime Algae (Cyanobacteria) Remover

For Mature Aquarium with Persistent Cyano

Red Slime Algae are unsightly, aggressive bacteria commonly found in marine aquarium.

Red Slime Algae can mostly be treated and kept under control by regular RedGone.

However, in some situation where the original attack was long standing and deeper substrate within the aquarium had been affected, the problem can return after effective treatment and persist.

REDGONE - Plus is specifically formulated to tackle such challenging problem in a mature well setup aquarium. It attacks cyanobacteria in a way similar to our regular RedGone but the additional ingredients ensures the treatment penetrate deep into the substrates and remove any hidden cyanobacteria within.

REDGONE - Plus can remove all traces of cyanobacteria deep into the substrates as well as surface deposits anywhere else in your aquarium with a single treatment.

- *Single unit treatment for up to **200 litres**
- *Reef & Coral safe; Fish safe; Invert safe
- *Safe for Nitrifying bacteria in a mature aquarium
- *Bio-degradable - no need for additional water change, protein skimming or aeration prior, during or after treatment
- *Contains No Algaecides or Erythromycin
- *Does not contain copper
- *Will not discolour aquarium water, does not stain equipments
- *Complete lasting removal - actively kills all traces of cyanobacteria hidden deep in the substrates
- *Visible result within days of treatment

REDGONE - Plus is specifically formulated to target and eliminate red slime algae (cyanobacteria) in a mature aquarium. To achieve optimum result it is important to achieve correct concentration within the aquarium.

It is formulated to target only red slime algae (cyanobacteria) and will not affect or treat other algae problem in the tank.

Instruction

1. First of all before the treatment, make sure you physically clear out the cyanobacteria slime as much as possible. Then do a water change according to normal routine.
2. Take 100ml of the tank water out in a small cup or jar.
3. Put all of the powder of one treatment in the water then mix thoroughly, ensuring all the powder is dissolved fully with no residue left. This makes 100ml of treatment solution.
4. Use table below to obtain correct amount of solution for tank size. For aquarium larger than 200L, more treatment is required to make up adequate treatment solution.
5. Slowly pour correct amount of solution into aquarium.
6. Ensure all filters and pumps are turned on in the aquarium to aid even distribution of solution.
7. Reduce feeding and lighting by @40% for 3 days. Skimmers and U/V steriliser can stay on as normal. Remove carbon filter or reactor during treatment.
8. Visible result should be visible within a few days. Treatment will continue to work in the background for 2 weeks, removing all traces of cyanobacteria in all nooks and cranny of the aquarium.
9. Continue normal water change and maintenance routine after the second week. Keep any remaining solution in the fridge if appropriate (in air tight container), or discard safely. With refrigeration they remain effective for around 6 weeks. (colour of solution may darken over time due to oxidation)

Aquarium Volume (L)	upto 50	50 -100	100 -150	150 - 200
Solution	25ml	50ml	75ml	100ml

Note:

Treatment will remove existing cyanobacteria from the current episode but it will not prevent new future attack from outside source. Good maintenance routine is required to minimise the chances of new future attacks.

Steps to take to prevent red slime algae:

1. Regular water change
2. Avoid over feeding
3. Good water movements with no stagnant area
4. Maintain PH 8.1-8.4
5. Minimise nutrients levels
